ABSTRACT

Aim: To assess the phyto diversity of pench tiger reserve, Maharashtra, India.

Place and Duration of Study: Pench Tiger Reserve (PTR), June 2022 to December 2023.

Methodology: The study was carried out by laying out quadratic sample plots in the PTR given by National Forest Inventory working plan code-2014 The plot size was 0.1 ha with 31.62 m x 31.62 m quadrats.

"Inventory List of Plant Diversity in Tropical Dry Deciduous Forest of Pench Tiger Reserve, Maharashtra, India". *International Journal of Plant & Soil Science* 36 (11):613-31. <https://doi.org/10.9734/ijpss/2024/v36i115174>.

Results: The study reveals a rich biodiversity comprising 863 species across 554 genera and 117 families, along with 8 varieties and 2 sub-species. The predominant taxa are herbs, accounting for 34.06% of species, followed by trees at 23.29%, climbers at 15.17%, grasses at 13.09%, sedges at 7.3%, epiphytic herbs at 0.8%, and bamboo at 0.2%. Fabaceae emerges as the most species-rich family in comparable studies, underscoring its ecological significance.

Conclusion: The study emphasizes the importance of comprehensive biodiversity inventories for understanding and conserving tropical forest ecosystems. This research provides valuable baseline data essential for future ecological studies, environmental assessments, and effective.

Keywords: Biodiversity; Central India; dry deciduous and pench tiger reserve.

1. INTRODUCTION

Tropical forests are considered the world's most biodiversity-rich ecosystems, vital for supporting the livelihoods of many, particularly in developing countries. Despite their significant roles in poverty alleviation, food security, and climate change resilience, these forests are often inadequately integrated into national development strategies (Nkem et al. 2007). Drivers of Biodiversity Loss A complex interplay of factors contributes to biodiversity loss in tropical forests. These include demographic changes, poverty, policy responses, ecological disturbances, anthropogenic disturbances, and climate change (Geist and Lambin 2002, Kolb and Diekmann 2004, Stork 2010). "In dry forest zones, specific threats such as wildfires, shifting cultivation, logging, and firewood extraction significantly increase the vulnerability of forest species through micro-environmental alterations affecting understory composition" (Chen et al. 1992). "The main drivers of biodiversity loss include deforestation, fragmentation, over-exploitation, invasive species, and climate change" (Gardner et al. 2009, Morris) with varying impacts across different tropical forest regions (Corlett and Primack 2008). Implications of Forest Degradation The ongoing destruction of tropical forests is expected to lead to an extinction crisis among forest species (Bradshaw et al. 2009). In India, native forests are reportedly declining at a rate of 3.5%, despite reforestation efforts that have increased total forest cover. This loss occurs when our understanding of forest structure and dynamics remains insufficient, which is crucial for sustainable management and conservation (Barthlott et al. 2007, Huang et al. 2003). Approaches to Restoring Biodiversity Restoring biodiversity in degraded landscapes is essential for the sustainability of native forests and ecosystem functionality. One method is allowing floristic recovery through natural succession, although this process can be hindered by factors such as

high land use intensity (Guariguata and Ostertag 2001) and limited seed availability for many tropical species (Wijdeven and Kuzee 2000) as well as competition for resources (Holl et al. 2000). Human intervention offers an alternative strategy for long-term biodiversity protection (Blakesley et al. 2000, Lamb et al. 2005). Importance of Biodiversity Inventories Intervention data are typically gathered through biodiversity inventories that assess the nature and distribution of biotic resources in the target area (Rennolls and Laumonier 2000). Plant checklists are essential for developing hypotheses related to large-scale ecological studies, biogeography, and environmental assessments (Hortal et al. 2015). "Flawed checklists can lead to misleading conclusions about biodiversity. Therefore, it is essential to gather reliable data on species composition, their vulnerabilities, and how they respond to climatic changes across various ecosystems. This information is critical for developing effective conservation strategies aimed at mitigating the degradation of natural resources. By ensuring accurate assessments, we can better understand the impacts of climate change on biodiversity and implement measures that protect and sustain our ecosystems. This study aims to address this need by generating baseline data on the native flora of the tropical forest ecosystem in central India".

2. MATERIALS AND METHODOLOGY

2.1 Study Area

The present study was carried out in the Pench Tiger Reserve, Maharashtra which is named after the Pench River, which is running through the Satpura's slowly southern hill ranges from North to South. Geographically, the Pench Tiger Reserve is located between 79°03'46" to 79°21'20" East to 21°11'58" to 21°43'16" North covers a total area of 741.22 km², including its core area (257.26 km²) and buffer area (483.96 km²) (Panda et al. 2013).

2.2 Methodology

The National Working Plan Code-2014 provides guidelines for the design and layout of these sample plots. This code specifies the use of square sample plots, which are essential for collecting data on forest carbon stocks. Upon arriving at the designated sampling plot location, a square plot measuring 0.1 hectares (31.62 m × 31.62 m) should be established. This involves measuring a horizontal distance of 22.36 meters half of the diagonal outward in all four directions: at 45° (northeast), 135° (southeast), 225° (southwest), and 315° (northwest) from true north. It is crucial to ensure the proper dimensions are maintained during this layout process. Additionally, subplots measuring 3 m × 3 m and 1 m × 1 m should be established 30 meters from the center of the main 0.1 ha plot in all directions. These subplots are designated for sampling shrubs, climbers, regeneration, and herbs/grasses, respectively. Furthermore, quadrats of sizes 1 m × 1 m, 3 m × 3 m, and 5 m × 5 m will be laid out in the northeast (NE) and southwest (SW) directions (NWPC 2014).

3. RESULTS AND DISCUSSION

The inventory assembled here revealed that Pench Tiger Reserve harbors 863 species belonging to 554 genera and 117 families, along with 8 varieties and 2 sub-species (Table 1). The major taxa assembled include Herbs with 294 species (34.06%), followed by Trees with 201 species (23.29%) of which Natural Trees account for 157 species (18.19%) and Avenue Trees for 44 species (5.09%). Other taxa include Climbers with 131 species (15.17%), Grasses with 113 species (13.09%), Sedges with 63 species (7.3%), Epiphytic Herbs with 7 species (0.8%), and Bamboo with 2 species (0.2%). Similar results were reported by Pratap Chandra Panda in his study on plant diversity in tropical deciduous forests of the Eastern Ghats, India, which revealed a total of 882 species belonging to 532 genera and 129 families. This study recorded 263 tree species, 78 species of shrubs, 138 species of climbers/twinners, and 403 species of herbs. The results of the study compare well with other large-scale inventories conducted in tropical forests both in India and

elsewhere. For instance, 63 species were recorded for a 50 ha plot at Mudumalai Forest Reserve, India, while 996 species were found in a 52 ha area at Lambir, Malaysia (Condit et al. 2000). A floristic inventory in Sri Lankamalleswara Wildlife Sanctuary, Andhra Pradesh resulted in 520 plant species with 133 tree species (17), and 60 ha of Nayagarh forests in the Northern Eastern Ghats yielded 177 tree species (Mastan and Reddy 2003). In the southern Eastern Ghats of Tamil Nadu, 272 tree species were recorded (21), and 71 tree species were identified in the dry deciduous forests of Mudumalai Wildlife Sanctuary (Sukumar et al. 1992). Similarly, in Nallamalais, a large-scale floristic assessment in 88 ha resulted in 729 herb species and 249 tree species (Basha 2009) while the Sheshachalam hill ranges featured 222 tree species (Babu and Rao 2010). These results indicate a higher level of tree species in tropical dry forests, as the assessments have covered different vegetation ranges from moist to dry forests along varied altitudes and disturbance levels. The dominant family in the reserve is Poaceae, with 118 species and 73 genera, followed by Fabaceae with 102 species and 59 genera, Cyperaceae with 61 species and 15 genera, Malvaceae with 38 species and 22 genera, Asteraceae with 33 species and 25 genera, Acanthaceae with 30 species and 16 genera, Convolvulaceae with 28 species and 13 genera, Apocynaceae with 26 species and 22 genera, Lamiaceae with 26 species and 20 genera, and Rubiaceae with 24 species and 19 genera. Among these families, five recorded varieties, with Rubiaceae and Cyperaceae each having 2 varieties, while Fabaceae, Apocynaceae, and Convolvulaceae each recorded 1 variety. Additionally, Apocynaceae and Convolvulaceae recorded 1 sub-species in each family. A similar study conducted by Mastan and Reddy, recorded 87 families, with Fabaceae emerging as the species-rich family, comprising 61 species (13%), which include 37 herbs, 14 vines, 6 trees, and 4 lianas. The Fabaceae family also includes the largest genus, *Crotalaria*, comprising 9 species, followed by *Indigofera* with 8 species, and both *Rhynchosia* and *Desmodium* endowed with 7 species each. Euphorbiaceae ranked as the second most dominant family with 42 species, followed by Acanthaceae with 37 species (Mastan and Reddy 2023).

4. CONCLUSION

The study conducted in Pench Tiger Reserve, Maharashtra, underscores the critical importance of comprehensive biodiversity inventories in understanding and conserving tropical forest ecosystems. Despite global and regional efforts in conservation, challenges such as deforestation, habitat fragmentation, and climate change continue to threaten biodiversity. By meticulously cataloging the native flora, this research contributes valuable baseline data, essential for future ecological studies, environmental assessments, and effective conservation strategies. Ultimately, this work serves as a foundation for further ecological research and underscores the urgent need for integrated strategies to preserve these biodiverse habitats.

DISCLAIMER (ARTIFICIAL INTELLIGENCE)

We, author(s) hereby declare that NO generative AI technologies such as Large Language Models (ChatGPT, COPILOT, etc) and text-to-image generators have been used during writing or editing of this manuscript.

ACKNOWLEDGEMENTS

We extend our special thanks to the State Forest Department of Maharashtra, India, for generously providing us with equipment and personnel help for conducting research.
